Introduction

Inverse problem of neutron stars: infer the equation of state (EOS) of dense nuclear matter from observations of neutron stars (NSs): masses, radii, tidal deformabilities, . . .

Bottleneck: solving Tolman-Oppenheimer-Volkoff (TOV) equations

Inverting neutron stars with differentiable programming

Our solution: differentiable programming with JAX [1]

- GPU accelerators no emulators required!
- Automatic differentiation to compute gradients of code

We efficiently invert neutron stars with

- 1 Bayesian inference: using NS data to constrain EOS parameters
- **2** Gradient-based optimizers: efficient inversion of R(M) or $\Lambda(M)$

Available open source: JESTER (Otsunhopang/jester)

Methods – Equation of state parametrization (1)

- At low density, we use the metamodel [2, 3]: Taylor expansion of energy per nucleon E/A in $x = (n n_{\rm sat})/3n_{\rm sat}$
- Nuclear empirical parameters (NEPs): coefficients of the expansion

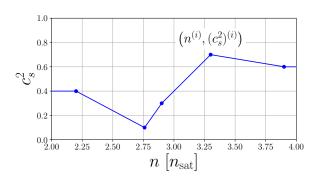

$$E/A(n,\delta) = e_{\mathrm{sat}}(n) + e_{\mathrm{sym}}(n)\delta^2 + \mathcal{O}(\delta^4), \quad \delta = (n_n - n_p)/n$$

$$\begin{split} e_{\rm sat}(n) &= E_{\rm sat} + \tfrac{1}{2} K_{\rm sat} x^2 + \tfrac{1}{3!} Q_{\rm sat} x^3 + \tfrac{1}{4!} Z_{\rm sat} x^4 + \mathcal{O}(x^5) \\ e_{\rm sym}(n) &= E_{\rm sym} + L_{\rm sym} x + \tfrac{1}{2} K_{\rm sym} x^2 \\ &+ \tfrac{1}{3!} Q_{\rm sym} x^3 + \tfrac{1}{4!} Z_{\rm sym} x^4 + \mathcal{O}(x^5) \end{split}$$

 $^{^{1}}n_{\rm sat} \equiv 0.16 \; {\rm fm}^{-3}$

Methods – Equation of state parametrization (2)

- Metamodel description breaks down at $\emph{n}_{
 m break} \sim [1,2] \ \emph{n}_{
 m sat}$
- Higher density: parametrize the EOS with $c_s^2(n)$ grid points and linear interpolation [4]

Bayesian inference

@ Gradient-based optimization

Results – Bayesian inference

- EOS constraints: nuclear theory ($\chi_{\rm EFT}$), NS observations (heavy PSRs, NICER, GW170817)
- Extend Koehn *et al.* [5]: directly sample $\theta_{\rm EOS}$
- \sim 0.24 ms per TOV solver call, \sim 1 h for MCMC run (H100 GPU)
- Scales well with number of parameters (more $c_s^2(n)$ grid points)

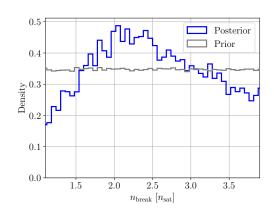

Constraint	$R_{1.4}~\mathrm{[km]}$			
	Koehn+	This work		
$\chi_{\rm EFT}$	$12.11^{+1.69}_{-3.39}$	$12.59^{+2.24}_{-3.51}$		
Radio timing	$13.70^{+1.41}_{-2.17}$	$13.71^{+1.19}_{-1.88}$		
PSR J0030+0451	$13.17^{+1.65}_{-2.24}$	$13.48^{+1.42}_{-2.15}$		
PSR J0740+6620	$13.39^{+1.57}_{-1.72}$	$13.79^{+1.26}_{-1.73}$		
$\rm GW170817^{\dagger}$	$11.98^{+1.08}_{-1.09}$	$12.40^{+1.33}_{-1.49}$		
All	$12.26^{+0.80}_{-0.91}$	$12.62^{+1.04}_{-1.11}$		

Results – Measuring n_{break}

 $\chi_{\rm EFT}$ predicts metamodel to break down at a density $n_{\rm break} \sim 1-2~n_{\rm sat}$ Can we determine this with NSs?

- Wide, agnostic prior on $n_{\rm break}$: U(1,4) $n_{\rm sat}$
- Only consider heavy PSRs, NICER, GW170817

Contents

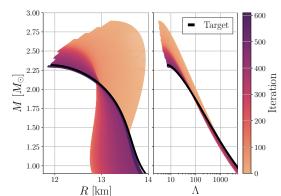

Bayesian inference

② Gradient-based optimization

Methods – Gradient-based optimization

- Given $\hat{\Lambda}_i$: "true" tidal deformabilities at masses M_i to invert
- ullet Loss function $L(heta_{
 m EOS})$: relative error in tidal deformability Λ
- Gradient descent: $\theta^{(i+1)} \leftarrow \theta^{(i)} \gamma \nabla L(\theta^{(i)})$ with Adam
 - Automatic differentation!

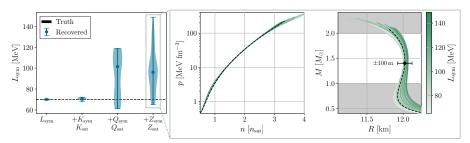

$$L(oldsymbol{ heta}_{\mathrm{EOS}}) = rac{1}{N} \sum_{i=1}^{N} \left| rac{\Lambda_i(oldsymbol{ heta}_{\mathrm{EOS}}) - \hat{\Lambda}_i}{\hat{\Lambda}_i}
ight|$$

Results – Recovery of nuclear empirical parameters

What do NSs tell us about nuclear empirical parameters (NEPs)?

- "True" EOS: only NEPs no $c_s^2(n)$ grid points
- Recover with increasingly more NEPs being varied
- ullet If more NEPs are varied, $L_{
 m sym}$ is no longer constrained
- Recovered EOSs deviate < 100 meters, < 10 in Λ from the true EOS observationally indistinguishable

Conclusion

- We have developed JESTER, a differentiable programming framework for the inverse problem of NSs
- We demonstrate accurate and scalable Bayesian inference on NS data
- Gradient-based optimizers can efficiently invert a complete NS family
- New tool to gain insights into how NSs probe the EOS
